

E1.7 Railway Jarvis Final Report

Date: 2026-07-03

Status: Done for production-current guarded cloud review flow; Review for full product runtime

Scope: hosted Jarvis API, dashboard API routing, agent-orchestra review packets, final Epic 1 runtime gate

Executive Result

E1.7 is complete for the production-current guarded cloud review-flow baseline. The exact public dashboard URL now points to the current Vercel production deployment, serves regenerated July 3 dashboard data, and exposes the same-origin Jarvis API. The Railway `jarvis-api` service was deployed from the service root with Nixpacks, reached running success state, and passed hosted HTTPS checks for health, CORS, chat, PRD/ICP, agent-orchestra, role config, role-update candidate, and voice-safe text routes.

This is not a full customer SaaS runtime yet. OpenRouter routing is wired and guarded, but live provider execution was blocked because copying the local OpenRouter key into Vercel/Railway external environment storage requires explicit credential-storage approval. Provider calls, durable writeback, raw voice storage, authenticated client portals, and persistent client data remain gated.

Proof Scorecard

Capability	Score	Visual	Current result
Hosted API availability	5/5	#####	Railway service running and health route passed
Provider safety	5/5	#####	MODEL_PROVIDER=openrouter, provider calls 0, provider execution blocked at missing approved server-side key
Writeback safety	5/5	#####	external writeback 0; dashboard writeback still gated
Dashboard routing	5/5	#####	public Vercel dashboard is current and same-origin API routes pass
Multi-agent control surface	4/5	####.	Architecture 2 packet route passes; real autonomous execution remains gated
Voice runtime	2/5	##...	text-only voice-safe packet passes; raw audio, STT, TTS, and storage are not productized
Product readiness	2/5	##...	backend proof exists; auth, persistence, billing, and customer workspaces are missing

Architecture Proven

- dashboard browser
 - > current Vercel production dashboard
 - > Vercel same-origin API and hosted Railway Jarvis API
 - > guarded OpenRouter review packet
 - > owner/Codex review before any durable write

Endpoint Evidence

Check	Result	Safe interpretation
Railway service status	Passed	latest deployment running successfully
Railway service domain	Passed	HTTPS domain generated and reachable
GET /health	Passed	runtime reports ok, provider openrouter, zero model calls, zero writeback
CORS preflight	Passed	Vercel dashboard origin allowed for POST traffic
POST /api/chat	Passed	returns review packet without provider call
GET /api/config/roles	Passed	role configuration available for dashboard control
POST /api/lanes/prd-icp	Passed	Architecture 1 PRD/ICP packet works
POST /api/lanes/agent-orchestra	Passed	Architecture 2 control packet works
POST /api/voice/chat	Passed	text-only voice packet works; no raw audio persistence
Deploy logs	Passed	server started on assigned Railway port
Recent HTTP error logs	Passed	no hosted HTTP errors returned for validation probes

Dashboard And Configuration

The dashboard now supports a configurable Jarvis API base URL stored only in the browser. The operator can:

- save a hosted backend origin;
- check hosted /health;
- export the dashboard configuration packet with the selected API base;
- send service-mode packets to /api/lanes/prd-icp;
- send control-mode packets to /api/lanes/agent-orchestra.

This makes the dashboard configurable without committing runtime URLs or secrets into the public repository.

Multi-Agent Architecture Status

Layer	Current state	Productization gap
Architecture 1: service workflow	PRD/ICP packet route passes on Railway	needs source-card persistence and auth
Architecture 2: control workflow	agent-orchestra packet route passes on Railway	needs durable role state, approvals, and audit log
LangGraph controller	represented as the safe control contract	not yet a live cloud state machine
CrewAI roles	role config and proof lane represented	not default autonomous runtime
WikiLLM/Notion/GitHub	updated by Codex after review	dashboard-driven writeback remains disabled

Current Service Representation

For ArchFlow, this setup represents a controlled PRD Pack operating system:

- source material becomes reviewed artifacts;
- review packets separate service workflow from system-control workflow;
- the KB update principle controls what becomes memory;
- the hosted API can receive dashboard packets without provider spend;
- Codex remains the responsible operator for durable writes.

For clients, this can be described as a gated productized service method, not yet as a self-serve SaaS:

- inputs are handled through a source-bound process;
- outputs are PRD, backlog, decisions, questions, risks, and handoff artifacts;
- AI output is review-gated;
- sensitive data and raw transcripts are not stored in the public proof system.

Critique

The main risk is overclaiming. The hosted runtime works, but it is intentionally narrow. It proves a safe backend bridge for review packets, not a complete cloud product. The next quality step is not more UI; it is auth, persistence, audit logging, provider budget ledgering, and a buyer-validated workflow from Epic 2.

Remaining Gates

Gate	Status	Required before Done
Provider-backed Jarvis	Gated	explicit approval to store the OpenRouter key in external runtime env, server-side secrets, budget ledger, sanitized input policy, owner approval
Durable writeback	Gated	authenticated action approvals, audit log, rollback policy
Raw voice/audio	Gated	raw audio policy, retention limits, STT/TTS provider decision
Client portal	Gated	auth, workspace isolation, data policy, billing path
Market proof	Gated	Epic 2/E6/E7 evidence and paid-intent test

Acceptance

E1.7 can move to Done for the production-current guarded cloud review flow. It should not move to Done for full cloud product runtime until the remaining gates are implemented and verified.
